

Systolic blood pressure is defined as the pressure in the arteries when the heart contracts, typically less than 140 millimeters of mercury (mmHg). The clinical range are, Normal is 90-119 mmHg. Pre-hypertension is 120–139 mmHg. Hypertension (high) is ≥ 140 mmHg. Hypotension (low) is < 90 mmHg. Values > 180 indicate a hypertensive crisis. Systolic Blood Pressure (SBP) is vital in the triage process because it serves as a primary indicator of hemodynamic stability and tissue perfusion. It helps triage nurses quickly detect life-threatening conditions like shock, severe sepsis, or internal hemorrhage, ensuring patients receive immediate, sight- or life-saving interventions.
